

A close-up photograph of a black rhinoceros, showing its thick, wrinkled skin and two large, dark horns. Two small, dark birds with red beaks (oxpeckers) are perched on the rhino's head and back. The background is a blurred natural setting.

Black rhino

By : the potatoes

introduction

- Black rhino's are the only rhino's that have a hook on their horn
- They are the most endangered species of the rhino family.
- They are the smallest among rhino's

habitat

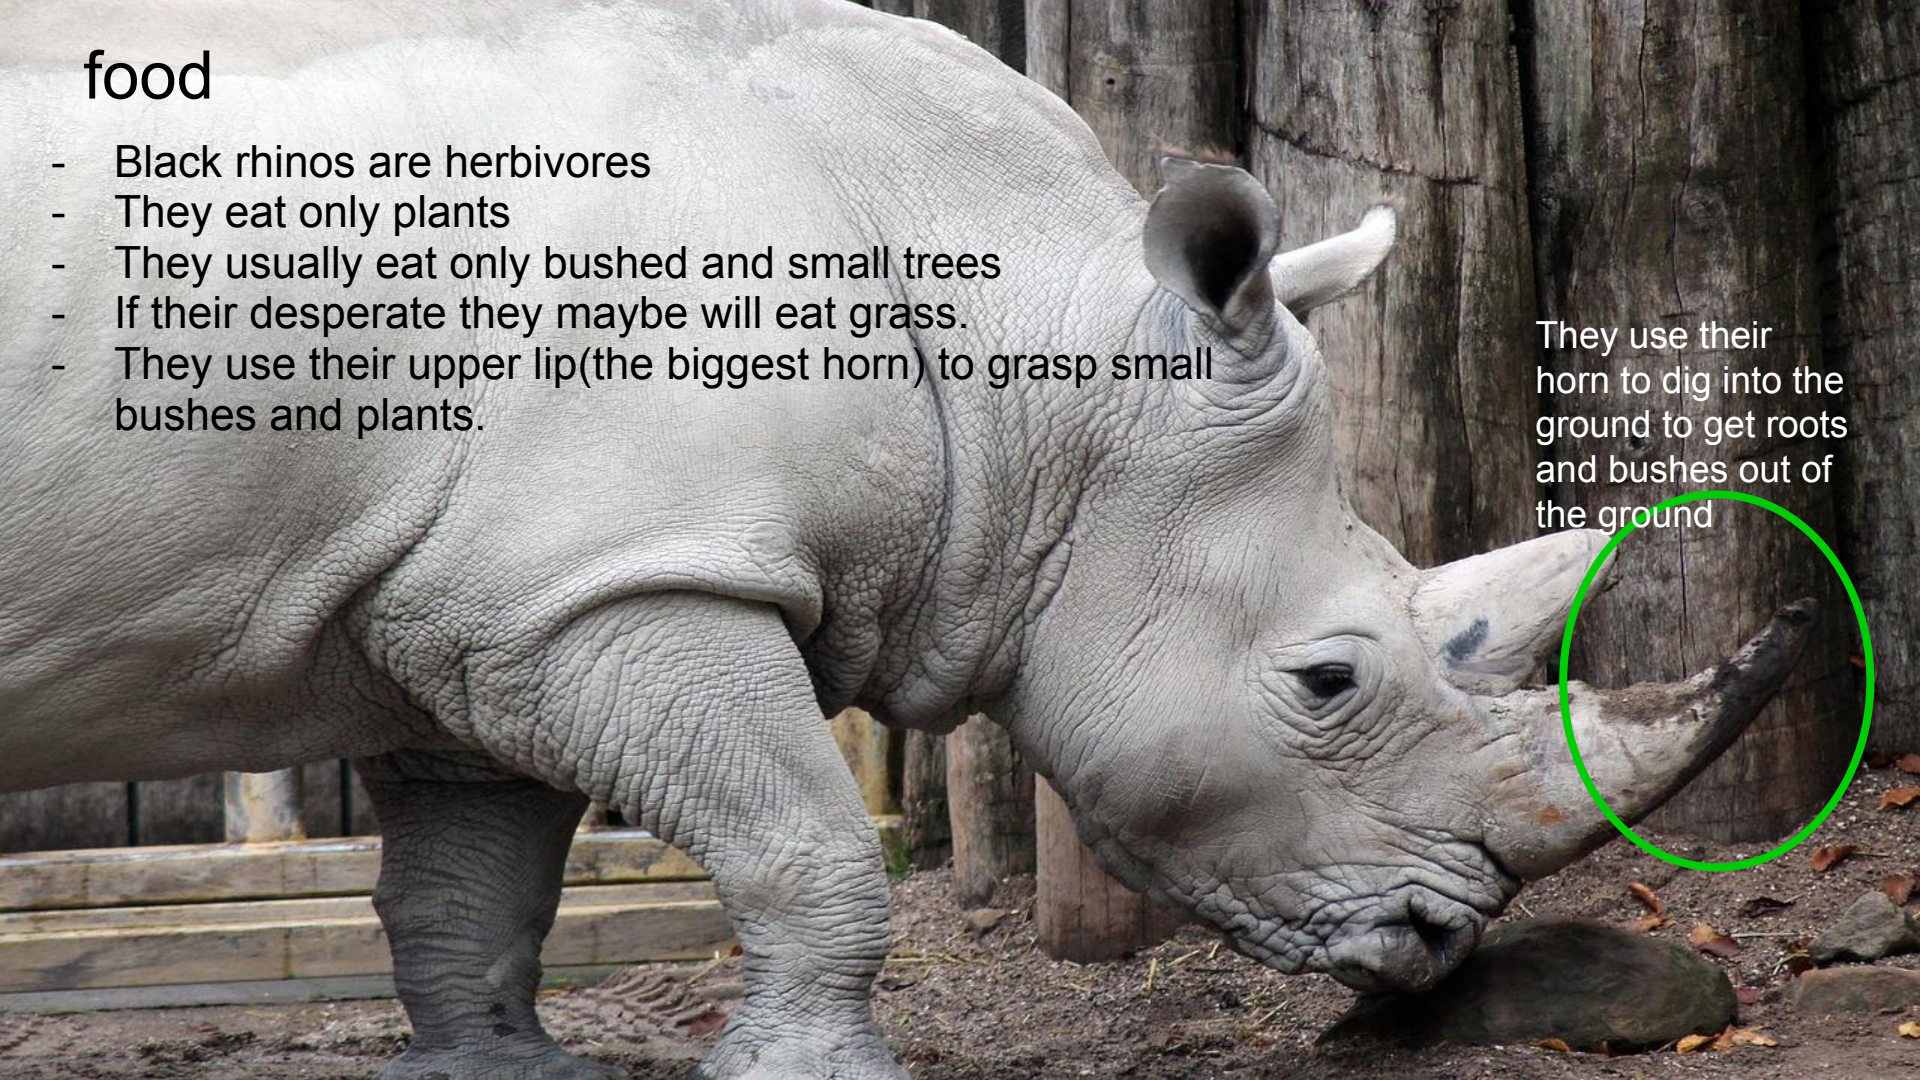

- Their habitat is in africa
- Their habitat covers about $\frac{1}{2}$ of africa
- The cause of being endangered isn't because of habitat destruction
- They mostly live in savannas and grasslands

food

- Black rhinos are herbivores
- They eat only plants
- They usually eat only bushes and small trees
- If their desperate they maybe will eat grass.
- They use their upper lip(the biggest horn) to grasp small bushes and plants.

They use their
horn to dig into the
ground to get roots
and bushes out of
the ground

How to replace

The biggest solution is to stop poaching them

We can replace other materials to make medicines

And protect them however we can

Why their endangered

Black rhinos are endangered because:

- Their poached for remedies
- Slaughtered for their horn
- They are especially poached in vietnam and china.

La population

Their are 5'000 black
rhinos left in the wild

That is certainly bad.
